

# Web Information Retrieval

M2R – MOSIG  
2019-2020

Philippe Mulhem

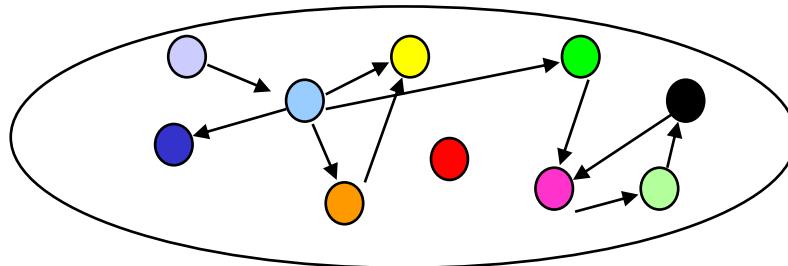

[Philippe.Mulhem@imag.fr](mailto:Philippe.Mulhem@imag.fr)  
<http://lig-membres.imag.fr/mulhem/>

# Outline

- The Web as a graph
- Web document access
  - Crawler/Indexing/Content Retrieval
  - Graph Usage
  - Integration of elements for Web retrieval
- Conclusion

# The Web as a graph

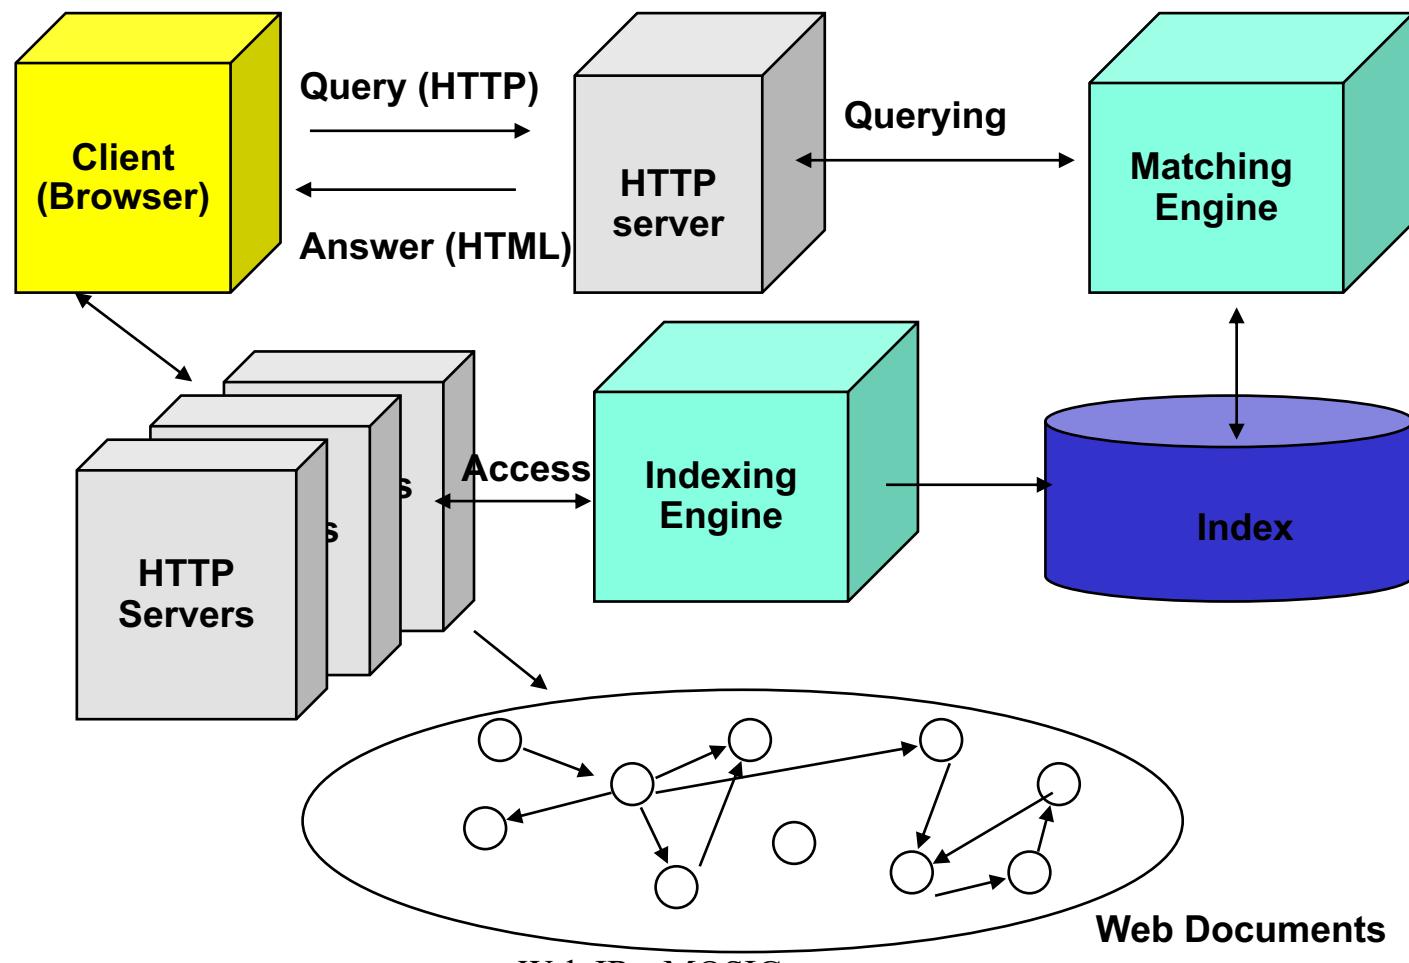

- Web : largest source of information
- Web pages: nodes
- Hypertext links: edges (meanings: structure, recommendation, similarity, reading paths ?)

- The graph structure may be used for IR access

# Web documents access

- Information available but not accessible... need for retrieval

# Web Retrieval by queries

- General features
  - Automatic indexing
    - Robust: heterogeneity (languages, documents structures & formats)
  - Coverage (Google : 45 billions of pages)
    - Huge storage capacity (hundreds of TeraBytes)
  - Freshness
  - Response time (for interaction, 4 billions queries/day)
    - Multi-level indexing (content and structure)
    - Huge processing
    - Models that mix content/structure/links (boolean models with words position, query logs, social data)

# Indexing engine - Crawler

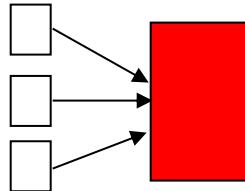

- Dynamic exploration of the web (bots)
  - Googlebot, Bingbot, Slurp (Yahoo), DuckDuckBot
- Simple crawler using a set of seeds URL named E
  - **while** E not empty **do**
    - e  $\leftarrow$  get\_one\_element\_of(E)
    - p  $\leftarrow$  get\_page\_from\_URL(e)
    - index(p)
    - E = E  $\cup$  outlinks(p)
  - Refinements on
    - Number of pages, Topics
    - Efficiency (wrt. overload of web servers)
- Classical inverted indexes with term position, adapted to high dimensions (terms x documents x queries)
  - Distributed indexes

# Content Retrieval

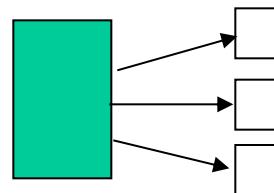

- Queries on the web are generally short (2-4 words)
- « The best place to hide a dead body is page 2 of the Google search results. » (Brian Clark)
  - people are interested in the first result page
    - All elements that may enhance the top-10 results are used (web server features, social tags, HTML validations, ...)
- Classical Boolean models with term position
  - AND/OR/NOT
  - Proximity search
- 100's of other parameters (not only content)

# Graph Usage – HITS [Kleinberg99]

- Goal: for a query (topic), to find
  - Good sources of content (Authorities, AUTH)

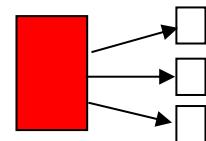

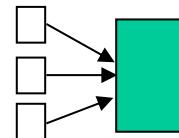

- Good sources of links (Hubs, HUB)

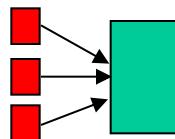

# Graph Usage – HITS [Kleinberg99]

- Pages characterized by  $\langle \text{HUB}; \text{AUTH} \rangle$  value  
→ Intuition

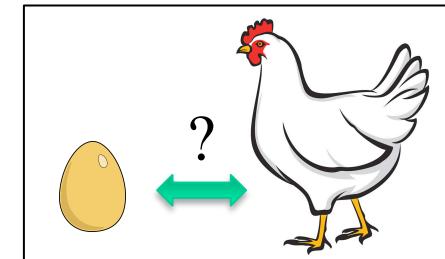

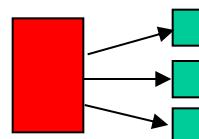

- Authority value from in-links
- Hub value from out-links

- High Authority if in-links from good Hubs

- High Hub if out-links to good Authorities

# Graph Usage – HITS [Kleinberg99]

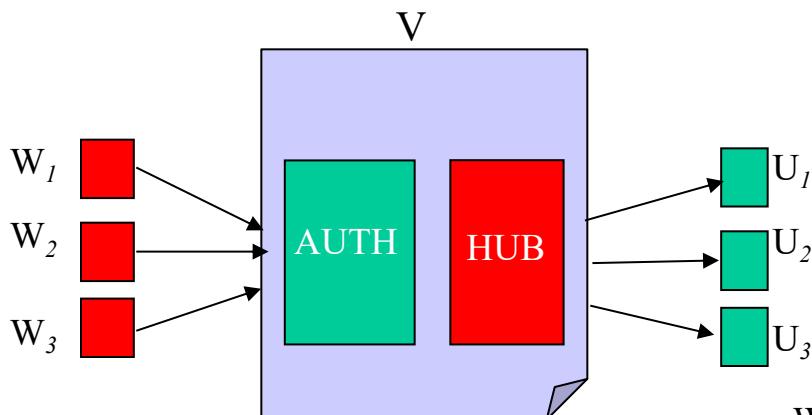

- Initialisation :
 
$$\sum AUTH[V]^2 = \sum HUB[V]^2 = 1 \quad (\text{if } N \text{ pages: } AUTH[V] = HUB[V] = \frac{1}{\sqrt{N}})$$
- Iteration until convergence

1. For each  $V$  : 
$$AUTH'[V] = \sum_{Edge(W_i, V)} HUB[W_i]$$

$$HUB'[V] = \sum_{Edge(V, U_i)} AUTH[U_i]$$

2. Normalization:

$$AUTH[V] = \frac{AUTH'[V]}{\sqrt{\sum_U AUTH'[U]^2}}$$

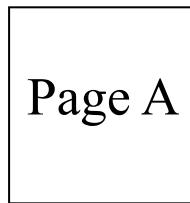

$$HUB[V] = \frac{HUB'[V]}{\sqrt{\sum_U HUB'[U]^2}}$$

so that  $\sum AUTH[U]^2 = \sum HUB[U]^2 = 1$

# Graph Usage – HITS [Kleinberg99]

- Example

- $\text{AUTH}[A]=\text{HUB}[A]=1$

# Graph Usage – HITS [Kleinberg99]

- Example

	AUTH[A]	HUB[A]	AUTH[B]	HUB[B]
0	0.71	0.71	0.71	0.71
1.1	0	0.71	0.71	0
1.2	0	1	1	0
2.1	0	1	1	0
2.2	0	1	1	0

$\sqrt{\sum AUTH'[U]^2}$	$\sqrt{\sum HUB'[U]^2}$
0.71	0.71
1	1

# Graph Usage – HITS [Kleinberg99]

- Example

	AUTH[A]	HUB[A]	AUTH[B]	HUB[B]	AUTH[C]	HUB[C]
0						
1.1	0.58	0.58	0.58	0.58	0.58	0.58
1.2	0	0.58	0	0.58	1.15	0
2.1	0	0.71	0	0.71	1	0
2.2	0	1	0	1	1.41	0
3	0	0.71	0	0.71	1	0

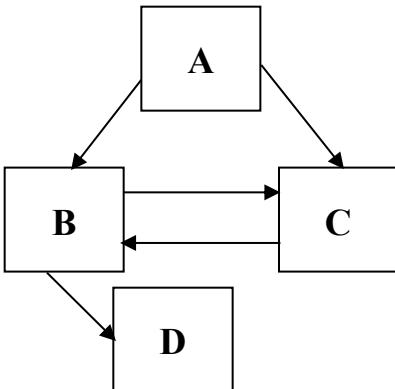

$\sqrt{\sum A[U]^2}$	$\sqrt{\sum H[U]^2}$
1.15	0.82
1.41	1.41
	3

# Graph Usage – HITS [Kleinberg99]

- Example

	AUTH[A]	HUB[A]	AUTH[B]	HUB[B]	AUTH[C]	HUB[C]
0	0,58	0,58	0,58	0,58	0,58	0,58
1,1	0	1,15	1,15	0,58	1,15	0,58
1,2	0	0,82	0,71	0,41	0,71	0,41
2,1	0	1,41	1,22	0,71	1,22	0,71
2,2	0	0,82	0,71	0,41	0,71	0,41

Note : stop when mean of differences  $\leq 0.02$

	AUTH[A]	HUB[A]	AUTH[B]	HUB[B]	AUTH[C]	HUB[C]	AUTH[D]	HUB[D]
0	0.5	0.5	0.5	0.5	0.5	0.5	0.5	0.5
1.1	0,00	1,00	1,00	1,00	1,00	0,50	0,50	0,00
1.2	0,00	0,67	0,67	0,67	0,67	0,33	0,33	0,00
2.1	0,00	1,33	1,00	1,00	1,33	0,67	0,67	0,00
2.2	0,00	0,74	0,56	0,56	0,74	0,37	0,37	0,00
3.1	0,00	1,30	1,11	1,11	1,30	0,56	0,56	0,00
3.2	0,00	0,72	0,62	0,62	0,72	0,31	0,31	0,00
4.1	0,00	1,34	1,03	1,03	1,34	0,62	0,62	0,00
4.2	0,00	0,74	0,57	0,57	0,74	0,34	0,34	0,00
5.1	0,00	1,32	1,09	1,09	1,32	0,57	0,57	0,00
5.2	0,00	0,73	0,60	0,60	0,73	0,32	0,32	0,00

# Graph Usage – HITS [Kleinberg99]

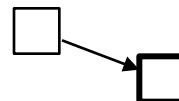

- Conclusion
  - Overload for each query processed
  - « Heavy » computation
  - Easy to spam with automatically generated links
- How to avoid these drawbacks ?
  - Pagerank

# Graph Usage – Pagerank

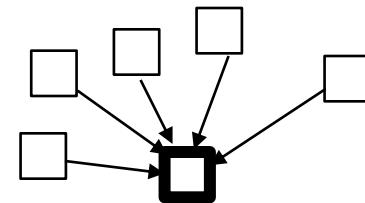

- Google [Brin & Page 1998]
  - Pagerank computes the popularity of web pages
    - +++) independently of any query
  - A Pagerank value is one positive floating point value
    - +++) simple
  - Graphically:

Low popularity

Medium popularity

High popularity

# Graph Usage – Pagerank

- All web pages vote for the popularity of one Web page.
- An in-link on a page is voting « for » the page.
- No link is an « abstention » about the page
- Pagerank computes the « chances » to access one page A from any other page on the web, according A's in-links

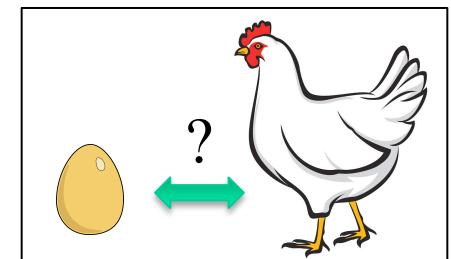

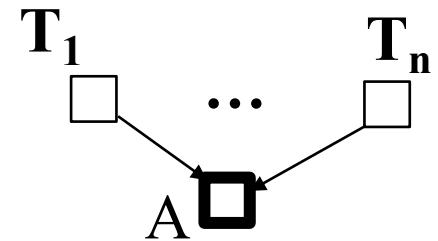

# Graph Usage – Pagerank

- The Pagerank, PR, of a page A is defined as:

$$PR(A) = (1 - d) + d * \left( \frac{PR(T_1)}{C(T_1)} + \dots + \frac{PR(T_n)}{C(T_n)} \right)$$

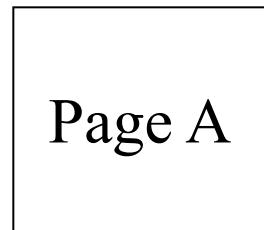

avec

- d : dumping factor in [0,1]
  - » 1-d chances to jump directly to A
  - » d chances to get to A through links
- $T_i$  : Web page that links to A
- $C(T_i)$  : number of out-links from  $T_i$
- PR in  $[1-d, +\infty[$
- How to compute  $PR(A)???$ 
  - Iteration until convergence, with initial values of 1.0

# Graph Usage – Pagerank

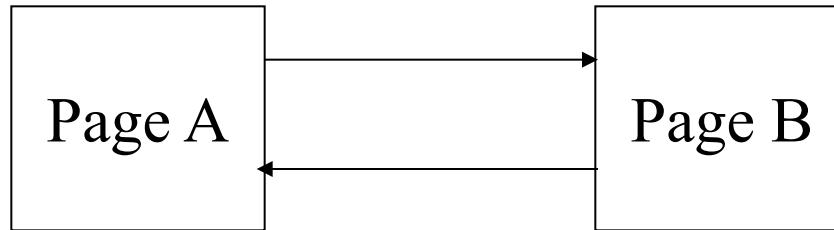

- Example

- $d=0.85$  and initial  $PR(A) = 1$
- $PR(A)=(1-d) = 0.15$

# Graph Usage – Pagerank

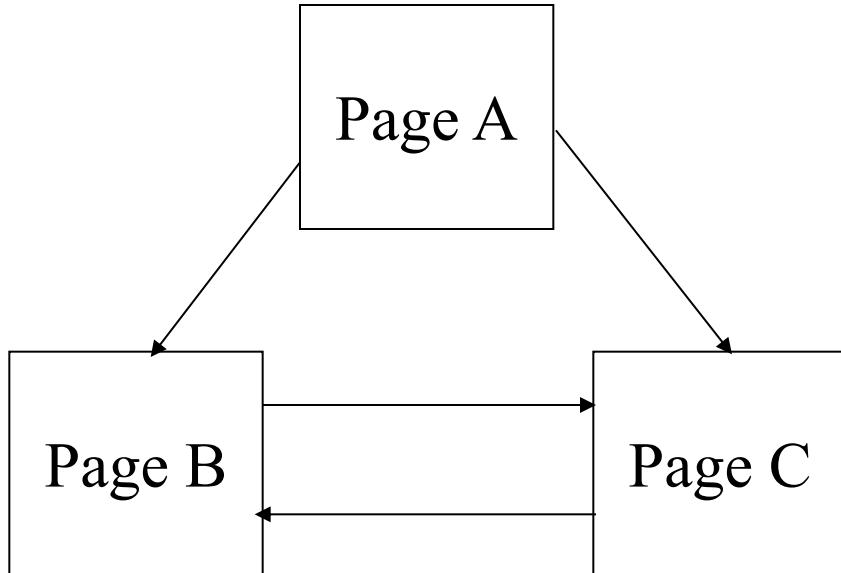

- Example

- $d=0.85$ , init  $PR(A) = PR(B) = 1$
- $PR(A) = (1-d) + d(PR(B)/1) = 0.15 + 0.85*1 = 1$
- $PR(B) = (1-d) + d(PR(A)/1) = 0.15 + 0.85*1 = 1$
- Initial values do not change in this case.

# Graph Usage – Pagerank

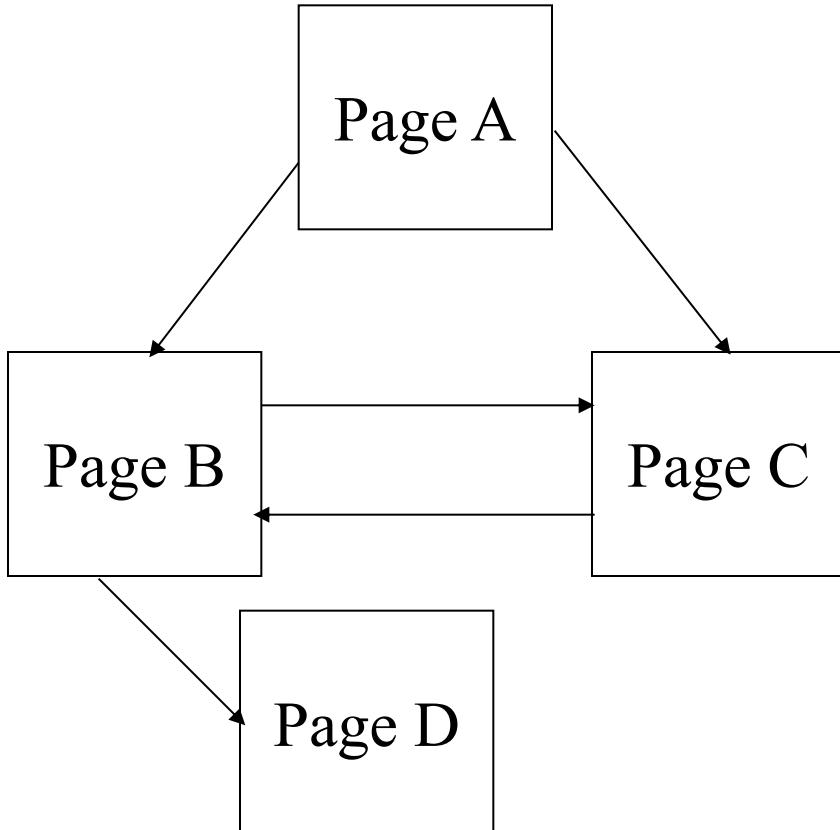

- Example
  - $d=0.85$ , init  $PR(A) = PR(B) = PR(C)=1$

	PR(A)	PR(B)	PR(C)
0	1	1	1
1	0,15	1,425	1,425
2	0,15	1,425	1,425

# Graph Usage – Pagerank

- Example

	PR(A)	PR(B)	PR(C)	PR(D)
0	1	1	1	1
1	0,15	1,425	1	0,575
2	0,15	1,06	0,82	0,76
3	0,15	0,91	0,67	0,60
4	0,15	0,78	0,60	0,54
5	0,15	0,72	0,55	0,48
6	0,15	0,68	0,52	0,46
7	0,15	0,66	0,50	0,44

Note : stop when average of differences lower than threshold 0,02.

# Graph Usage – Pagerank

- Example ([www.iprcom.com/papers/pagerank plus actif](http://www.iprcom.com/papers/pagerank_plus_actif))
  - Simple hierarchy

# Graph Usage – Pagerank

- Conclusion
  - + A priori computation
  - + Hard to spam
  - Complex to compute on billions of pages
  - Disadvantages novelty
  - Choice of one interpretation of links

# Integration of elements for Web retrieval

- Integration with content-based matching using learning to rank

- Letor 3.0 GOV corpus

[Qin, Liu, Xu, Li 2010]

- 64 features
- 575 queries
- Features of top 1000 docs

49	HITS authority	Q-D
50	HITS hub	Q-D

# Integration of elements for Web retrieval

- Ex.: Learning to rank using logistic regression (Pointwise)
- Idea : to learn the best combination of coefficients using a set of values to estimate relevance
  - Example (2 params (ex. <PageRank, BM25> as <x1, x2>, 3 coeffs for the learned function) :  $\text{output(item)} \leftarrow b_0 + b_1 \cdot x_1 + b_2 \cdot x_2$  (1)
    - Logistic regression:  $p(\text{class}=1|\text{item}) = 1 / (1+e^{-\text{output(item)}})$  (2)
  - Iteration (e.g. using stochastic Gradient Descent)
    1. Output using current values of coefficients
    2. Re-estimate coeffs based on the prediction error (i items with class  $Y_i$ , j coeffs, m learning rate parameter)
$$b_j' = b_j - m \cdot \sum_i ((p(\text{class} = 1 | \text{item}_i) - Y_i) \cdot \text{item}_{i,j}) \quad (3)$$
  - Decision :
    - if  $P(\text{class}=1) > 0.5$  then  $\text{decision}=1$   
else  $\text{decision}=0$

# Integration of elements for Web retrieval

## Input

(Y == relevant)

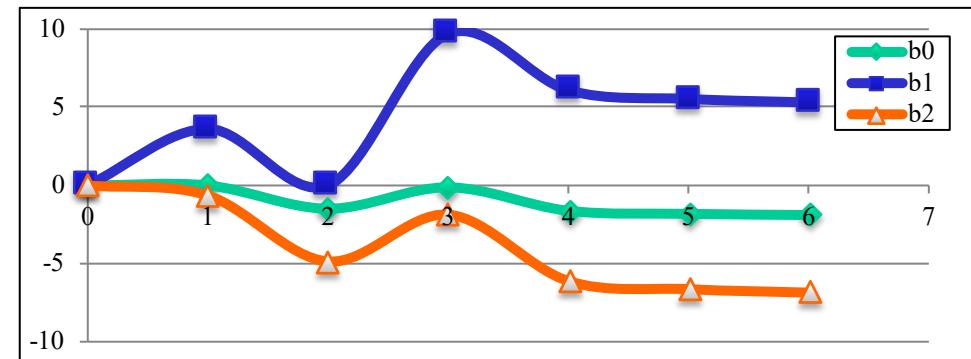

Item id	x1	x2	Y
0	2,781	2,551	0
1	1,465	2,362	0
2	3,397	4,400	0
3	1,388	1,850	0
4	3,064	3,005	0
5	7,628	2,759	1
6	5,332	2,089	1
7	6,923	1,771	1
8	8,675	-0,242	1
9	7,674	3,509	1

init :  $b_1 = b_2 = b_3 = 0.0$

At the end of epoch 6 :

epoch	b0	b1	b2
6	-1,739	4,140	-7,267

## Optimization ( $m=0.3$ )

Item Id	Y	P(class = 1)	decision
0	0	0,034	0
1	0	0,001	0
2	0	0,001	0
3	0	0,011	0
4	0	0,207	0
5	1	1	1
6	1	1	1
7	1	1	1
8	1	1	1
9	1	1	1

# Integration of elements for Web Retrieval

- Others factors
  - Correlation study [http://www.searchmetrics.com/wp-content/uploads/Ranking\\_Correlations\\_EN\\_print.pdf](http://www.searchmetrics.com/wp-content/uploads/Ranking_Correlations_EN_print.pdf)
  - Guesses on Google <http://backlinko.com/google-ranking-factors>
  - User data (clicks, ...)
  - Site speed, extension
  - Pages : number of backlinks, size
  - Social : refs in Twitter, Google+ ...

# Conclusion

- Short view of web retrieval techniques
  - Web search specificities
- For meta-search (fusion of runs from several search engines), Learning to Rank can be used
- Research problems
  - Integration of users input (logs) to enhance results
  - Dimensionality (users, web pages, queries, languages, dynamicity)
  - Integration of content and semantics (RDF Resource Description Framework)

# Work to be done

- Compute the values en HUB/AUTH + Pagerank on the slides example
- Look at Letor 3.0 and learning to rank papers, redo the example.
